Problems with
explainability

References

Overview

- The “computational approach” here: machine learning, applied to social data
- Won’t discuss simulation modeling, the other computational approach
- I assume:
 - Familiarity with social statistics/ econometrics
 - Some familiarity with R (for demo/tutorial)
- Focus on key conceptual and practical things, usually covered poorly
 - When should we use machine learning? How do we use it?

Road map

- Going from statistics to machine learning
- When is machine learning appropriate?
 - “Prediction” problems
- Model selection in machine learning
 - Cross-validation
- Model evaluation in machine learning
 - Setting aside a test set
- Demonstration in

Defining machine learning

Statistics:

Machine learning:

Machine learning: An instrumental use of statistical correlations to *mimic* the output of a target process, rather than understand the *relationship* between inputs and outputs. Involves finding expressions that maximize correlation.

Breiman 2001. See also Jones 2018.

Why are these different goals?

The surprising part

- *The best-fitting* (most accurate*) model does not necessarily reflect how the world works
- This has been shocking in statistics for decades (Stein's paradox, Leo Breiman's "two cultures"), but little known outside
- Why: one reason is the "bias-variance tradeoff"
 - Even when available, the "true" covariates may be noisy, in which case proxies (or even just going with the mean) sometimes does better
- We can use correlations to "predict" without knowing causality, or "explaining"!

* Or other relevant metric of success

But: can't *intervene* based on correlations

- Very different sets of correlations can “predict” equally well (Mullainathan & Spiess, 2017)
- But they would suggest very different interventions

So what is ML useful for? Building systems

- Recommend/narrow people's choices to "relevant" ones (friend connections, search results, products)
- Detection (facial, fraud)
- Anticipation (customer demand, equipment failure)
- It "works"...

- ML overlaps lots with *nonparametric statistics*, which (for example) gets models by locally smoothing input data rather than getting global fits. But ML also uses parametric models, and lots of Bayesian models (although in decidedly non-Bayesian ways)
- ML: no statistical inference, and so doesn't need to calculate standard errors. Opens up modeling possibilities
- ML: focuses on *classification*, i.e. categorical responses. This is easier (only need to be on the correct side of the true underlying decision boundary)
- Even just in terms of pure model fit, does ML beat stats for social questions? Not always! (Junqué de Fortuny et al. 2013; Salganik et al. 2020)
 - Note: deep learning only works for audio, images, and (sometimes) time series. For general modeling, random forests are usually best (Caruana et al. 2008; Fernández-Delgado et al., 2014)
- Caution: statistical significance is not the same as feature importance!

Key components of a good use case

1. We have reliable “ground truth” (e.g., human labels, previous failures/fraud);
2. “Ground truth” is hard to collect;
3. In the future or other contexts, “ground truth” is unknown but could be used if known;
4. We have some readily available proxy measure; and
5. *We don't care how or what in the proxy recovers the “ground truth”, only that it does*

If we care about relationships between inputs and outputs, ML is useless (except for exploration)

ML model = “Ground truth” + proxy

- Correlate known values/labels with available proxy for unknown values/labels
- Find *decision boundary/criterion/threshold*. Use this to treat new observations
- Shift that boundary to prioritize certain metrics
- Most ML is basically this!

Key points

- Machine learning should not be used to say something about the way the world works; it should only be used instrumentally
- Machine learning is like training to win a race, so it's only meaningful if we actually run the race
- (More on this later): *machine learning performance claims are always preliminary until we do real-world testing*

What good is machine learning for social science?

- For exploratory analysis, especially of “high-dimensional data”
 - Topic models for text corpuses
- Nonparametric models (which may be labeled as “machine learning” but, if they quantify uncertainty, I’d call them statistical) are useful for modeling complex bivariate relationships.
 - Substantive analysis and interpretation can only be done visually, so it’s not really useful beyond bivariate relationships

What good is machine learning in social science?

- For scaling up human labels to a larger dataset
 - Let's say you have 1m tweets
 - Hand-code 1000 tweets between 3 coders, coding for whatever you care about, and make sure Cohen's kappa is sufficient as usual
 - Extract " n -gram" features
 - Fit a random forest to 500 observations; test on the remaining 500; report the accuracy, precision, and recall
 - Re-train a model with all 1000 labeled cases, use that to make "predicted" labels for the remainder of the data
 - Then you can make frequency statements about the presence of codes within the 1m tweets
 - Ideally, also give confidence intervals that take into account the uncertainty of the imperfect model, and lack of perfect agreement among coders

What good is machine learning in social science?

- Graphical models are part of machine learning, and can express complex causal structure (are equivalent to Structural Equation Models)
- Note: can express causal structure, not find/discover it
 - And ultimately “expresses” causality in a very limited way (Hu 2019a, 2019b, 2020; Richardson 2021)
- But within machine learning, graphical models are seldom used for causal modeling

References

Overfitting: fit to noise

- If we are no longer guided by theory, and use flexible, automatic methods, we risk *overfitting*: fitting to the noise, not the signal ("memorizing the data"). Applies to ML and nonparametric stats

Data splitting: Catch overfitting

- Idea: if we split data into two parts, the signal should be the same but the noise would be different
- *Cross validation*: Fitting the model on one part of the data, and “testing” on the other

Doing data splitting correctly

- Data splitting is used for two distinct things in machine learning: model selection and model evaluation
 - Selection could be between *model class*, like between a logistic regression and a decision tree; or it could be selection of *tuning parameters*, like the bandwidth of local polynomial regression
- They have very different theoretical properties
- For both: *want to split in a way that respects dependencies*
- E.g., random splits of a time series means you use future values to “predict” past ones
 - “Time-traveling”
 - Not a realistic test of out-of-sample performance

Who perished on the Titanic? The importance of social norms

Bruno S. Frey
University of Warwick, Coventry

David A. Savage and Benno Torgler
Queensland University of Technology, Australia

Abstract
This paper seeks to empirically identify what factors make it more or less likely for people to survive in a life-threatening situation. These factors relate to individual incentives, social norms, and the role of social support and social networks. The basic idea is that individuals act according to their personal incentives and social norms. Some norms become apparent in such a dangerous situation. The empirical analysis supports the notion that social norms are key determinants in survival situations of life or death.

Keywords
survival, under pressure, disasters, power, game-theoretical experiments, survival, tragic events

I Situations of life or death
This paper asks the question: what individual factors determine survival in a situation of life or death? The basic idea is that individuals act according to their personal incentives and social norms. Some norms become apparent in such a dangerous situation. The empirical analysis supports the notion that social norms are key determinants in survival situations of life or death.

Behavior under Extreme Conditions: The Titanic Disaster

Bruno S. Frey, David A. Savage, and Benno Torgler

During the night of April 14, 1912, the RMS *Titanic* collided with an iceberg, resulting in the sinking of the ship and the loss of over 1,500 lives. This is one of the greatest tragedies. This creates one of the deadliest maritime disasters in history and is far the most tragic. The disaster came as a great shock because the ship was considered unsinkable. The sinking of the *Titanic* has been analyzed by many economists, and was thought to be purely an "unintended" (although the belief that the ship was unsinkable was widespread) consequence of the economic system (explained, e.g., in Hayek, 1959). The *Titanic* case was reanalyzed by the economist James G. Hansen (1992), who argued that the disaster was caused by the lack of safety norms and safety, the way it would be found from the *Titanic*, *A Night to Remember* (1958), *The泰坦尼克号沉没之谜* (1997), *Die Katastrophe der Titanic* (1998), *Das Untergang der Titanic* (1998), and of course the 1997 movie, directed by James Cameron and starring Leonardo DiCaprio and Kate Winslet. The movie was a massive commercial success, and it joined Anne Michel and Dr. Robert Ballard, located the wreckage and recovered approximately 3,500 artifacts, which were later shown in an exhibition that toured the world.

■ Bruno S. Frey is Professor of Economics, Institute for Empirical Research in Economics, University of Zurich, and a Research Fellow at the Center for Economic Policy Research, London Business School, University of Warwick, U.K. David A. Savage is a Graduate Student, School of Economics and Finance, Queensland University of Technology, Brisbane, Australia. Benno Torgler is Associate Professor of Economics, University of Queensland, St. Lucia, Australia. Frey, Savage, and Torgler are also associated with CREMA—Center for Research in Economics, Management and the Arts, Zurich, Switzerland.

- Machine learning is structured very similarly to statistics
- But we only care about something very narrow, and something different from what we care about when doing statistics (or narrative)
 - What would this even generalize to? Predicting death from sinkings of other 19th-century cruise liners?
 - Meta-commentary: this dataset exists because of effort put in by people in the cultural wake of a movie!
 - I would speculate this is used as an exercise because it gives a feeling of power over life and death
- Data splitting shouldn't be done lightly
 - Siblings fall along different sides of test splits, and they may have survived together
- Test performance is almost certainly than training performance—and out-of-sample performance is almost certainly always worse than test performance

*if male and adult then survival probability 21% (19%–23%)
else if 3rd class then survival probability 44% (38%–51%)
else if 1st class then survival probability 96% (92%–99%)
else survival probability 88% (82%–94%)*

- Decision list: interpretable and explainable
- Lethan, Rudin et al.: “For example, we predict that a passenger is less likely to survive than not because he or she was in the 3rd class.”
- “Because” the model, or “because” the world?

But ML is correlations, not causes

- Finale Doshi-Velez & Been Kim: “one can provide a feasible explanation that fails to correspond to a causal structure, exposing a potential concern.”
- Rich Caruana et al.: “Because the models in this paper are intelligible, it is tempting to interpret them causally. Although the models accurately explain the predictions they make, they are still based on correlation.”
- Zachary Lipton: “Another problem is that such an interpretation might explain the behavior of the model but not give deep insight into the causal associations in the underlying data... The real goal may be to discover potentially causal associations that can guide interventions.”

Wish list for interpretability

- Face validity as a way to check the model
- Anticipate where the model might break down (e.g., when it fails face validity)
- Use domain knowledge to 'fine-tune' the model
