Key points

Theory:

- RFID and Bluetooth sensors *measure* proximity, which can be a proxy for the construct of interaction
- But proximity is also important as a construct

Practice:

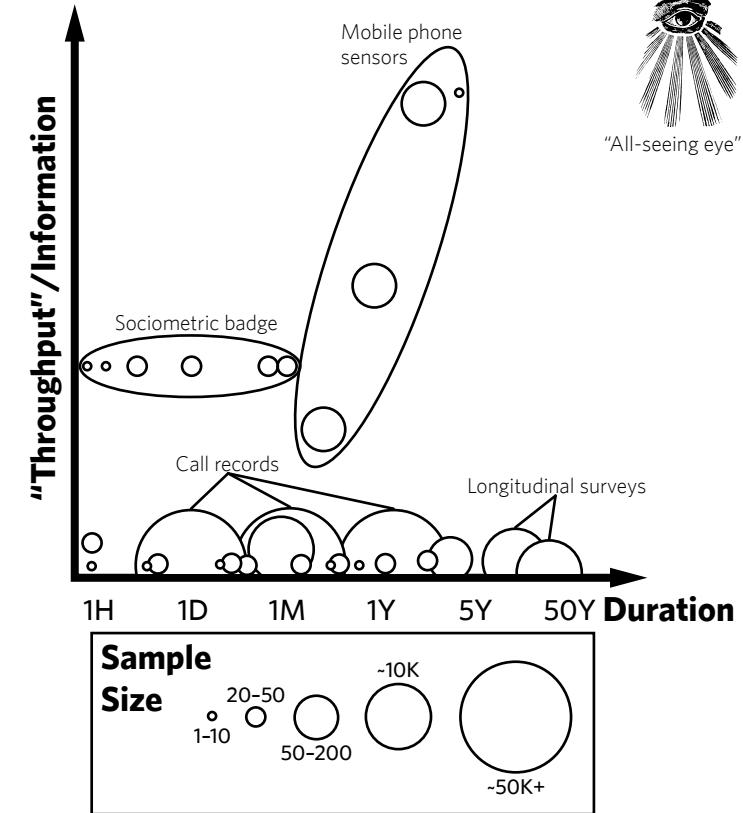

- Compare sensors to other data (e.g., survey data)
- Reduce sensor data by “feature extraction” and variable selection, done with careful cross-validation

Summary

Inconsistent terminology suggests confusion

- Copenhagen Networks Study (Bluetooth):
 - “Proximity data”¹
 - “Face-to-face interactions”²
 - “Close proximity interactions”³
 - “Face-to-face contacts”⁴
 - “Physical contacts”⁵
- SocioPatterns papers (RFID):
 - “Person-to-person interaction”⁶
 - “Face-to-face contacts”⁷
 - “Close-range interactions”⁸
 - “Face-to-face interactions”⁹
 - “Face-to-face proximity”¹⁰
- Audio:
 - “Face-to-face conversation”¹¹

Back to basics: Constructs.

- *Constructs*: primitives of social science
 - A measurement might be a *proxy* for an non-observable construct (e.g., multiple choice questions and intelligence)
 - Proxies always give errors (binary construct: false negatives and false positives)
 - (Criterion-related [“predictive”] validity)
- Face-to-face interaction: neither the measure nor the construct

Summary

Constructs have their own importance

- What construct do we care about?
- Depends on what we want to study/investigate.
 - Disease transmission? Directional proximity and/or physical contact.
 - Persuasion? Conversation.
 - Mimicry? Interaction.
 - Latent homophily, expressed geographically? Proximity.
 - Environmental exposure? Proximity.

Survey data, too, has its own importance

- “Objective” sensor data is not superior to survey data
 - Yes, informant inaccuracy, social desirability bias, ambiguous questions...
- But they are measuring *different things*
 - Surveys better measure the *psychological perceptions* that may ultimately be causal for behavior¹ (e.g., memorability²)
- So, discrepancies must not be resolved in favor of the “objective” data
- Discrepancies are exactly the interesting thing to study!!
- Propinquity is an example (discrepancy is “close strangers, distant friends”³)

Proximity is itself interesting (propinquity!)

Summary

Data: Surveys + mobile phone tracking

Goal: Study propinquity

- Not proximity as proxy for interaction, but proximity itself
- Compare proximity (via “location”, WiFi) to longitudinal sociometric choice
- Look at proximity at scales larger than that of interaction
 - Small scales (proximity at <10m): underlying causal mechanism might still be interaction.
 - Large scales (proximity >20m): will capture other mechanisms, e.g. latent homophily, common environmental exposure, etc.

Core problem: *Different resolutions*

Summary

Approach: First do machine learning

- Step 1: Find out how to meaningfully characterize the association of proximity and friendship
- Step 2: Using this characterization, model co-evolution

Summary

"Probability of proximity" (Reality Mining¹) Median pairwise distance (our study)

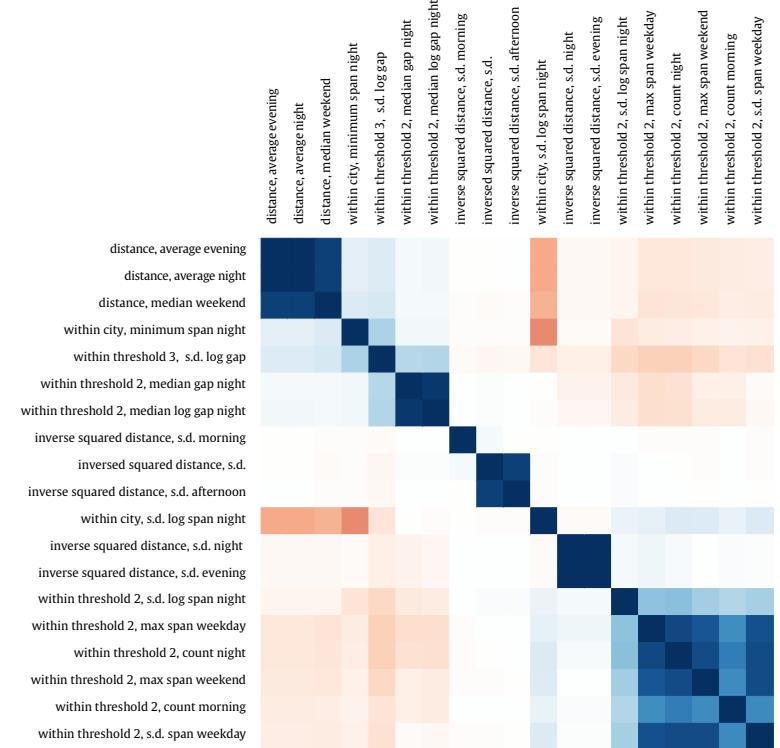

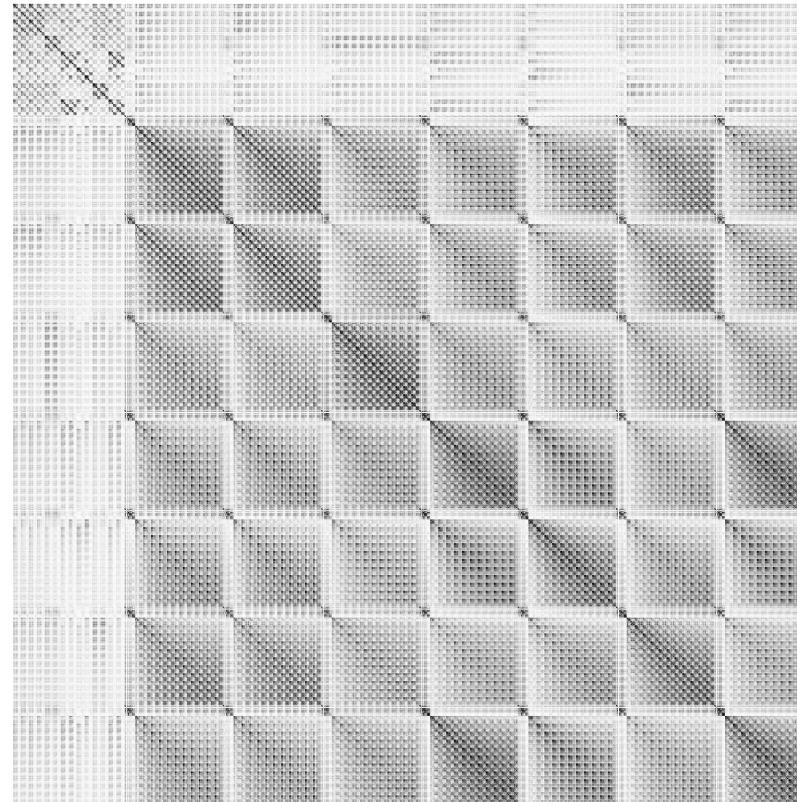

We found what looked like a compelling pattern as well, but it proved ineffective for prediction when tested with cross-validation. Why? Aggregate trends obscure between-dyad and week-to-week variance.

Test the performance via *cross-validation*

- Split data into “training” and “test”
- Fit model on training, evaluate on test
- Done correctly, simulates out-of-sample data, thereby directly establishing external validity
- But dependencies (e.g. time, networks) can complicate cross-validation
- We use multiple cross-validation schema to control for this (details in forthcoming work)

Result: ~30% association. Can get with 2.5K features... or 19, after feature selection.

Summary: How we *should* use sensors

- If using Bluetooth, RFID proxies for interaction, do more testing against human-coded benchmarks
- But *proximity* is also inherently interesting
- Compare proximity other forms of data (e.g., friendship for propinquity/influence vs. exposure)
- Comparing sensor data and survey data, e.g. via SAOMs, is a good framework
- Reduce/summarize rich signals through feature extraction + selection, not naïve aggregation

Thank you!
